$\S 1$  GB.RAND RANDOM GRAPHS 1

Important: Before reading GB\_RAND, please read or at least skim the program for GB\_GRAPH.

1. Random graphs. This GraphBase module provides two external subroutines called random\_graph and random\_bigraph, which generate graphs in which the arcs or edges have been selected "at random." A third subroutine, random\_lengths, randomizes the lengths of the arcs of a given graph. The performance of algorithms on such graphs can fruitfully be compared to their performance on the nonrandom graphs generated by other GraphBase routines.

Before reading this code, the reader should be familiar with the basic data structures and conventions described in GB\_GRAPH. The routines in GB\_GRAPH are loaded together with all GraphBase applications, and the programs below are typical illustrations of how to use them.

```
#define random\_graph r\_graph /* abbreviations for Procrustean external linkage */#define random\_bigraph r\_bigraph
#define random\_lengths r\_lengths

\langle \text{gb\_rand.h} \ 1 \rangle \equiv
#define random\_graph r\_graph /* users of GB_RAND should include this header info */#define random\_bigraph r\_bigraph
#define random\_lengths r\_lengths

extern Graph *random\_graph();
extern Graph *random\_bigraph();
extern long random\_lengths();
```

2. Here is an overview of the file gb\_rand.c, the C code for the routines in question.

**3.** The procedure  $random\_graph(n, m, multi, self, directed, dist\_from, dist\_to, min\_len, max\_len, seed)$  is designed to produce a pseudo-random graph with n vertices and m arcs or edges, using pseudo-random numbers that depend on seed in a system-independent fashion. The remaining parameters specify a variety of options:

```
multi \neq 0 permits duplicate arcs;

self \neq 0 permits self-loops (arcs from a vertex to itself);

directed \neq 0 makes the graph directed; otherwise each arc becomes an undirected edge;

dist\_from and dist\_to specify probability distributions on the arcs;

min\_len and max\_len bound the arc lengths, which will be uniformly distributed between these limits.
```

If  $dist\_from$  or  $dist\_to$  are  $\Lambda$ , the probability distribution is uniform over vertices; otherwise the dist parameter points to an array of n nonnegative integers that sum to  $2^{30}$ , specifying the respective probabilities (times  $2^{30}$ ) that each given vertex will appear as the source or destination of the random arcs.

A special option multi = -1 is provided. This acts exactly like multi = 1, except that arcs are not physically duplicated in computer memory—they are replaced by a single arc whose length is the minimum of all arcs having a common source and destination.

The vertices are named simply "0", "1", "2", and so on.

2 RANDOM GRAPHS GB\_RAND §4

4. Examples:  $random\_graph(1000, 5000, 0, 0, 0, \Lambda, \Lambda, 1, 1, 0)$  creates a random undirected graph with 1000 vertices and 5000 edges (hence 10000 arcs) of length 1, having no duplicate edges or self-loops. There are  $\binom{1000}{2} = 499500$  possible undirected edges on 1000 vertices; hence there are exactly  $\binom{499500}{5000}$  possible graphs meeting these specifications. Every such graph would be equally likely, if  $random\_graph$  had access to an ideal source of random numbers. The GraphBase programs are designed to be system-independent, so that identical graphs will be obtained by everybody who asks for  $random\_graph(1000, 5000, 0, 0, 0, \Lambda, \Lambda, 1, 1, 0)$ . Equivalent experiments on algorithms for graph manipulation can therefore be performed by researchers in different parts of the world.

The subroutine call  $random\_graph(1000, 5000, 0, 0, 0, \Lambda, \Lambda, 1, 1, s)$  will produce different graphs when the random seed s varies; however, the graph for any particular value of s will be the same on all computers. The seed value can be any integer in the range  $0 \le s < 2^{31}$ .

To get a random directed graph, allowing self-loops and repeated arcs, and with a uniform distribution on vertices, ask for

$$random\_graph(n, m, 1, 1, 1, \Lambda, \Lambda, 1, 1, s).$$

Each of the m arcs of that digraph has probability  $1/n^2$  of being from u to v, for all u and v. If self-loops are disallowed (by changing '1, 1, 1' to '1, 0, 1'), each arc has probability  $1/(n^2 - n)$  of being from u to v, for all  $u \neq v$ .

To get a random directed graph in which vertex k is twice as likely as vertex k+1 to be the source of an arc but only half as likely to be the destination of an arc, for all k, try

```
random\_graph(31, m, 1, 1, 1, d0, d1, 0, 255, s)
```

where the arrays  $d\theta$  and d1 have the static declarations

```
long d\theta[31] = \{ \text{\#20000000}, \text{\#10000000}, \dots, 4, 2, 1, 1 \}; \}
long dt[31] = \{ 1, 1, 2, 4, \dots, \text{\#10000000}, \text{\#200000000} \}; \}
```

then about 1/4 of the arcs will run from 0 to 30, while arcs from 30 to 0 will be extremely rare (occurring with probability  $2^{-60}$ ). Incidentally, the arc lengths in this example will be random bytes, uniformly distributed between 0 and 255, because  $min\_len = 0$  and  $max\_len = 255$ .

If we forbid repeated arcs in this example, by setting multi = 0, the effect is to discard all arcs having the same source and destination as a previous arc, regardless of length. In such a case m had better not be too large, because the algorithm will keep going until it has found m distinct arcs, and many arcs are quite rare indeed; they will probably not be found until hundreds of centuries have elapsed.

A random bipartite graph can also be obtained as a special case of  $random\_graph$ ; this case is explained below.

Semantics: If multi = directed = 0 and  $self \neq 0$ , we have an undirected graph without duplicate edges but with self-loops permitted. A self-loop then consists of two identical self-arcs, in spite of the fact that multi = 0.

 $\S5$  GB.RAND RANDOM GRAPHS 3

5. If the  $random\_graph$  routine encounters a problem, it returns  $\Lambda$ , after putting a code number into the external variable  $panic\_code$ . This code number identifies the type of failure. Otherwise  $random\_graph$  returns a pointer to the newly created graph and leaves  $panic\_code$  unchanged. The  $gb\_trouble\_code$  will be cleared to zero after  $random\_graph$  has acted.

```
#define panic(c) { panic\_code = c; gb\_trouble\_code = 0; return \Lambda; }
\langle \text{External functions 5} \rangle \equiv
  Graph *random\_graph(n, m, multi, self, directed, dist\_from, dist\_to, min\_len, max\_len, seed)
       unsigned long n;
                              /* number of vertices desired */
                               /* number of arcs or edges desired */
       unsigned long m;
       long multi;
                       /* allow duplicate arcs? */
                      /* allow self loops? */
       long self;
       long directed;
                        /* directed graph? */
                            /* distribution of arc sources */
       long * dist\_from;
       long * dist_to;
                          /* distribution of arc destinations */
       long min_len, max_len;
                                  /* bounds on random lengths */
       long seed;
                      /* random number seed */
  { \langle Local variables 6 \rangle
    if (n \equiv 0) panic(bad_specs);
                                     /* we gotta have a vertex */
    if (min_len > max_len) panic(very_bad_specs); /* what are you trying to do? */
    if (((unsigned long)(max\_len)) - ((unsigned long)(min\_len)) > ((unsigned long) #8000000))
       panic(bad\_specs + 1);
                               /* too much range */
    (Check the distribution parameters 11);
    gb\_init\_rand(seed);

     if (multi \le 0) (Search for duplicate arcs or edges; goto repeat or done if found 10);
     if (directed) gb\_new\_arc(u, v, rand\_len);
     else gb\_new\_edge(u, v, rand\_len);
  done:;
This code is used in section 5.
```

 $\S10$  GB\_RAND RANDOM GRAPHS 5

10. When we decrease the length of an existing edge, we use the fact that its two arcs are adjacent in memory. If  $u \equiv v$  in this case, we encounter the first of two mated arcs before seeing the second; hence the mate of the arc we find is in location a + 1 when  $u \leq v$ , and in location a - 1 when u > v.

We must exit to location trouble if memory has been exhausted; otherwise there is a danger of an infinite loop, with  $dummy\_arc \neg next = dummy\_arc$ .

```
\langle Search for duplicate arcs or edges; goto repeat or done if found 10\rangle
  if (gb_trouble_code) goto trouble;
  else { register Arc *a;
                     /* length of new arc or edge being combined with previous */
     long len;
     for (a = u \rightarrow arcs; a; a = a \rightarrow next)
       if (a \rightarrow tip \equiv v)
          if (multi \equiv 0) goto repeat;
                                                /* reject a duplicate arc */
          else {
                      /* multi < 0 */
             len = rand_len;
             if (len < a \rightarrow len) {
               a \rightarrow len = len;
               if (\neg directed) {
                  if (u \le v) (a+1)-len = len;
                  else (a-1)-len = len;
             }
             goto done;
```

This code is used in section 9.

11. Nonuniform random number generation. The random\_graph procedure is complete except for the parts that handle general distributions dist\_from and dist\_to. Before attempting to generate those distributions, we had better check them to make sure that the specifications are well formed; otherwise disaster might ensue later. This part of the program is easy.

```
\langle Check the distribution parameters 11 \rangle \equiv
                              /* sum of probabilities */
  { register long acc;
                             /* pointer to current probability of interest */
    register long *p;
    if (dist_from) {
       for (acc = 0, p = dist\_from; p < dist\_from + n; p++) {
         if (*p < 0) panic(invalid_operand); /* dist_from contains a negative entry */
         if (*p > #40000000 - acc) panic(invalid_operand + 1);
                                                                       /* probability too high */
       if (acc \neq \text{\#40000000}) panic (invalid\_operand + 2); /* dist\_from \text{ table doesn't sum to } 2^{30} */
    if (dist_to) {
       for (acc = 0, p = dist_{-}to; p < dist_{-}to + n; p \leftrightarrow) {
         if (*p < 0) panic(invalid_operand + 5); /* dist_to contains a negative entry */
         if (*p > #40000000 - acc) panic(invalid_operand + 6);
                                                                        /* probability too high */
         acc += *p;
       if (acc \neq \text{\#40000000}) \ panic(invalid\_operand + 7); /* dist\_to \ table \ doesn't \ sum \ to \ 2^{30} \ */
  }
```

This code is used in section 5.

6

12. We generate nonuniform distributions by using Walker's alias method (see, for example, Seminumerical Algorithms, second edition, exercise 3.4.1–7). Walker's method involves setting up "magic" tables of length nn, where nn is the smallest power of 2 that is  $\geq n$ .

```
format magic_entry int
\langle \text{Local variables } 6 \rangle + \equiv
                      /* this will be increased to 2^{\lceil \lg n \rceil} */
  long nn = 1;
  long kk = 31;
                      /* this will be decreased to 31 - \lceil \lg n \rceil *
  magic_entry *from_table, *to_table;
                                                 /* alias tables */
      \langle Build tables for nonuniform distributions, if needed 13 \rangle \equiv
13.
     if (dist_from) {
       while (nn < n) nn += nn, kk --;
       from\_table = walker(n, nn, dist\_from, new\_graph);
     if (dist_to) {
       while (nn < n) nn += nn, kk --;
       to\_table = walker(n, nn, dist\_to, new\_graph);
     if (gb_trouble_code) {
       gb\_recycle(new\_graph);
       panic(alloc\_fault);
                                /* oops, we ran out of memory somewhere back there */
  }
This code is used in section 5.
```

This code is used in section 9.

```
14. \langle Private declarations 8 \rangle + \equiv
  typedef struct {
                     /* a probability, multiplied by 2^{31} and translated */
    long prob;
                    /* index that might be selected */
    long inx;
  } magic_entry;
15. Once the magic tables have been set up, we can generate nonuniform vertices by using the following
code:
\langle Generate a random vertex u according to dist_from 15\rangle \equiv
  { register magic_entry *magic;
     register long uu = gb\_next\_rand();
                                                /* uniform random number */
    k = uu \gg kk;
     magic = from\_table + k;
    if (uu \leq magic \neg prob) u = new\_graph \neg vertices + k;
     else u = new\_graph \neg vertices + magic \neg inx;
This code is used in section 9.
16. \langle Generate a random vertex v according to dist\_to 16 \rangle \equiv
  { register magic_entry *magic;
    register long uu = gb\_next\_rand();
                                                /* uniform random number */
     k = uu \gg kk;
     magic = to\_table + k;
    if (uu \leq magic \neg prob) v = new\_graph \neg vertices + k;
     else v = new\_graph \neg vertices + magic \neg inx;
```

8

17. So all we have to do is set up those magic tables. If uu is a uniform random integer between 0 and  $2^{31}-1$ , the index  $k = uu \gg kk$  is a uniform random integer between 0 and nn-1, because of the relation between nn and kk. Once k is computed, the code above selects vertex k with probability  $(p+1-(k \ll kk))/2^{31}$ , where  $p = magic \neg prob$  and magic is the kth element of the magic table; otherwise the code selects vertex  $magic \neg inx$ . The trick is to set things up so that each vertex is selected with the proper overall probability.

Let's imagine that the given distribution vector has length nn, instead of n, by extending it if necessary with zeroes. Then the average entry among these nn integers is exactly  $t=2^{30}/nn$ . If some entry, say entry i, exceeds t, there must be another entry that's less than t, say entry j. We can set the jth entry of the magic table so that its prob field selects vertex j with the correct probability, and so that its inx field equals i. Then we are selecting vertex i with a certain residual probability; so we subtract that residual from i's present probability, and repeat the process with vertex j eliminated. The average of the remaining entries is still t, so we can repeat this procedure until all remaining entries are exactly equal to t. The rest is easy.

During the calculation, we maintain two linked lists of (prob, inx) pairs. The hi list contains entries with prob > t, and the lo list contains the rest. During this part of the computation we call these list elements 'nodes', and we use the field names key and j instead of prob and inx.

```
\langle Private declarations 8 \rangle + \equiv
  typedef struct node_struct {
                    /* a numeric quantity */
     long key;
                                      /* the next node on the list */
     struct node_struct *link;
                  /* a vertex number to be selected with probability key/2^{30} */
  } node:
  static Area temp_nodes;
                                    /* nodes will be allocated in this area */
  static node *base_node;
                                   /* beginning of a block of nodes */
18. \langle \text{Internal functions } 18 \rangle \equiv
  static magic_entry *walker(n, nn, dist, g)
       long n;
                     /* length of dist vector */
                     /* 2^{\lceil \lg n \rceil} */
       long nn;
       register long *dist;
                                   /* start of distribution table, which sums to 2^{30} */
                       /* tables will be allocated for this graph's vertices */
       Graph *g;
  { magic_entry *table;
                                 /* this will be the magic table we compute */
                 /* average key value */
                                    /* nodes not yet included in magic table */
     node *hi = \Lambda, *lo = \Lambda;
                                   /* pointer variables for list manipulation */
     register node *p, *q;
     base\_node = gb\_typed\_alloc(nn, \mathbf{node}, temp\_nodes);
     table = gb\_typed\_alloc(nn, \mathbf{magic\_entry}, g \neg aux\_data);
     if (\neg gb\_trouble\_code) {
       \langle \text{Initialize the } hi \text{ and } lo \text{ lists } 19 \rangle;
       while (hi) \langle Remove a lo element and match it with a hi element; deduct the residual probability
               from that hi element 20\rangle;
       while (lo) \langle Remove a lo element of key value t 21\rangle;
     qb\_free(temp\_nodes);
                        /* if gb_trouble_code is nonzero, the table is empty */
     return table;
This code is used in section 2.
```

```
19. \langle \text{Initialize the } hi \text{ and } lo \text{ lists } 19 \rangle \equiv t = \#4000000/nn; /* \text{ this division is exact } */p = base\_node;
while (nn > n) {
p \text{-} key = 0;
p \text{-} link = lo;
p \text{-} j = --nn;
lo = p \text{++};
}
for (dist = dist + n - 1; \ n > 0; \ dist --, p \text{++}) {
p \text{-} key = * dist;
p \text{-} j = --n;
if (* dist > t) p \text{-} link = hi, hi = p;
else p \text{-} link = lo, lo = p;
}
This code is used in section 18.
```

**20.** When we change the scale factor from  $2^{30}$  to  $2^{31}$ , we need to be careful lest integer overflow occur. The introduction of register x into this code removes the risk.

 $\langle$  Remove a lo element and match it with a hi element; deduct the residual probability from that hi element 20  $\rangle$   $\equiv$ 

```
{ register magic_entry *r; register long x; p = hi, hi = p\text{-}link; \\ q = lo, lo = q\text{-}link; \\ r = table + q\text{-}j; \\ x = t * q\text{-}j + q\text{-}key - 1; \\ r\text{-}prob = x + x + 1; \\ r\text{-}inx = p\text{-}j; \\ /* \text{ we have just given } q\text{-}key \text{ units of probability to vertex } q\text{-}j, \text{ and } t - q\text{-}key \text{ units to vertex } p\text{-}j */ \text{ if } ((p\text{-}key -= t - q\text{-}key) > t) \text{ } p\text{-}link = hi, hi = p; \\ \text{else } p\text{-}link = lo, lo = p; \\ }
```

This code is used in section 18.

**21.** When all remaining entries have the average probability, the *inx* component need not be set, because it will never be used.

This code is used in section 18.

10

## 22. Random bipartite graphs. The procedure call

```
random\_bigraph(n1, n2, m, multi, dist1, dist2, min\_len, max\_len, seed)
```

is designed to produce a pseudo-random bipartite graph with n1 vertices in one part and n2 in the other, having m edges. The remaining parameters multi, dist1, dist2,  $min\_len$ ,  $max\_len$ , and seed have the same meaning as the analogous parameters of  $random\_graph$ .

In fact,  $random\_bigraph$  does its work by reducing its parameters to a special case of  $random\_graph$ . Almost all that needs to be done is to pad dist1 with n2 trailing zeroes and dist2 with n1 leading zeroes. The only slightly tricky part occurs when dist1 and/or dist2 are null, since non-null distribution vectors summing exactly to  $2^{30}$  must then be fabricated.

```
\langle \text{External functions 5} \rangle + \equiv
  Graph *random\_bigraph(n1, n2, m, multi, dist1, dist2, min\_len, max\_len, seed)
      unsigned long n1, n2;
                                   /* number of vertices desired in each part */
                               /* number of edges desired */
      unsigned long m;
      long multi;
                       /* allow duplicate edges? */
                              /* distribution of edge endpoints */
      long * dist1, * dist2;
      long min_len, max_len; /* bounds on random lengths */
                    /* random number seed */
      long seed;
  { unsigned long n = n1 + n2; /* total number of vertices */
    Area new\_dists;
    long * dist\_from, * dist\_to;
    Graph *new\_graph;
    init_area(new_dists);
    if (n1 \equiv 0 \lor n2 \equiv 0) panic(bad_specs); /* illegal options */
    if (min\_len > max\_len) panic(very\_bad\_specs); /* what are you trying to do? */
    if (((unsigned long)(max\_len)) - ((unsigned long)(min\_len)) \ge ((unsigned long) #8000000))
                                /* too much range */
      panic(bad\_specs + 1);
    dist\_from = gb\_typed\_alloc(n, \mathbf{long}, new\_dists);
    dist\_to = gb\_typed\_alloc(n, \mathbf{long}, new\_dists);
    if (gb\_trouble\_code) {
      qb\_free(new\_dists);
      panic(no\_room + 2);
                                /* no room for auxiliary distribution tables */
    \langle Compute the entries of dist_from and dist_to 23\rangle;
    new\_graph = random\_graph(n, m, multi, 0_L, 0_L, dist\_from, dist\_to, min\_len, max\_len, seed);
    sprintf(new_graph→id, "random_bigraph(%lu,%lu,%lu,%d,%s,%s,%ld,%ld,%ld)",
         n1, n2, m, multi > 0 ? 1 : multi < 0 ? -1 : 0, dist_code(dist1), dist_code(dist2),
         min\_len, max\_len, seed);
    mark\_bipartite(new\_graph, n1);
    gb\_free(new\_dists);
    return new_graph;
```

23. The relevant identity we need here is the replicative law for the floor function:

$$\left\lfloor \frac{x}{n} \right\rfloor + \left\lfloor \frac{x+1}{n} \right\rfloor + \dots + \left\lfloor \frac{x+n-1}{n} \right\rfloor = \left\lfloor x \right\rfloor.$$

This code is used in section 22.

12 RANDOM LENGTHS GB\_RAND §24

## 24. Random lengths. The subroutine call

```
random\_lengths(g, directed, min\_len, max\_len, dist, seed)
```

takes an existing graph and assigns new lengths to each of its arcs. If  $dist = \Lambda$ , the lengths will be uniformly distributed between  $min\_len$  and  $max\_len$  inclusive; otherwise dist should be a probability distribution vector of length  $max\_len - min\_len + 1$ , like those in  $random\_graph$ .

If directed = 0, pairs of arcs  $u \to v$  and  $v \to u$  will be regarded as a single edge, both arcs receiving the same length.

The procedure returns a nonzero value if something goes wrong; in that case, graph g will not have been changed.

Alias tables for generating nonuniform random lengths will survive in  $g \rightarrow aux\_data$ .

```
\langle \text{External functions 5} \rangle + \equiv
  long random_lengths(g, directed, min_len, max_len, dist, seed)
                        /* graph whose lengths will be randomized */
       Graph *g;
       long directed;
                          /* is it directed? */
                                     /* bounds on random lengths */
       long min_len, max_len;
                        /* distribution of lengths */
       long *dist;
                       /* random number seed */
       long seed;
  { register Vertex *u, *v; /* current vertices of interest */
                         /* current arc of interest */
     register Arc *a;
     long nn = 1, kk = 31;
                                /* variables for nonuniform generation */
     magic\_entry * dist\_table;
                                     /* alias table for nonuniform generation */
                                                 /* where is q? */
     if (q \equiv \Lambda) return missing_operand;
     gb\_init\_rand(seed);
     if (min_len > max_len) return very_bad_specs; /* what are you trying to do? */
     \mathbf{if} \ (((\mathbf{unsigned} \ \mathbf{long})(\mathit{max\_len})) - ((\mathbf{unsigned} \ \mathbf{long})(\mathit{min\_len})) \geq ((\mathbf{unsigned} \ \mathbf{long}) \ ^{\#}80000000))
       return bad_specs;
                               /* too much range */
     (Check dist for validity, and set up the dist_table 26);
     sprintf(buffer, ", %d, %ld, %ld, %s, %ld)", directed ? 1:0,
          min\_len, max\_len, dist\_code(dist), seed);
